New protocol using unfractionated heparin for radial-access percutaneous coronary intervention in acute coronary syndrome

Stormi E. Gale, PharmD, Catherine F. Salvador, PharmD, Jeannie L. Poon, PharmD
Novant Health Presbyterian Medical Center, Charlotte, NC

Background

- Bivalirudin and unfractionated heparin (UFH) are the two most commonly used anticoagulant medications in percutaneous coronary intervention (PCI)
- Trials have shown conflicting data regarding which anticoagulant is superior regarding efficacy and safety
  - ACUITY-ACS: Bivalirudin similar in efficacy to UFH with significantly less bleeding
  - HORIZONS-AMI: Decrease in all-cause and cardiovascular death but increased risk of stent thrombosis with bivalirudin
  - BRIGHT: Decrease in adverse clinical events with bivalirudin over both UFH plus tirofiban and UFH alone
  - HEAT-PPCI: Reduction in major adverse cardiac events (MACE) including acute stent thrombosis and reinfarction with UFH; no difference in bleeding
  - MATRIX: Reduction in mortality and bleeding but increase in stent thrombosis with bivalirudin as compared to UFH

- Novant Health (NH) facilities utilized bivalirudin in approximately 90% of PCI cases prior to implementation of a new PCI protocol
- PCI protocol at NH was altered to employ heparin as the preferred anticoagulant in radial-access PCI in April 2015

Methods

- Study Design
  - Retrospective, single center, IRB-approved chart review
  - Pre-implementation: April 2014 through July 2014
  - Post-implementation: April 2015 through July 2015

- Inclusion Criteria
  - Patients ≥ 18 years of age
  - ICD-9 and ICD-10 codes for ACS
  - Radial-access PCI
  - Pre-implementation group given bivalirudin during PCI
  - Post-implementation group given heparin during PCI

- Endpoints
  - Primary: MACE at 30 days
  - Secondary: (a) Incidence of major bleeding within 72 hours post-PCI; (b) Protocol compliance; (c) 30-day readmission; (d) Concurrent antithrombotic medication(s)
  - Wilcoxon-rank sum to evaluate continuous variables
  - X² or Fisher’s exact for categorical variables
  - Alpha=0.05

Preliminary Results

- Bivalirudin utilization in 91% of PCI cases prior to implementation of new protocol; heparin utilized in 73% of cases post-implementation

<table>
<thead>
<tr>
<th></th>
<th>Pre-implementation (n=91)</th>
<th>Post-implementation (n=106)</th>
</tr>
</thead>
<tbody>
<tr>
<td>MACE at 30 days</td>
<td>0.9% (n=1)</td>
<td>3.2% (n=3)</td>
</tr>
<tr>
<td>Major bleeding within 72 hours post-PCI</td>
<td>8.5% (n=9)</td>
<td>8.8% (n=11)</td>
</tr>
</tbody>
</table>

- Non-adherence to protocol identified in 36.6% of cases post-implementation of which, 29.7% (n=11) were under dosed

 ACT Range with Heparin in Radial PCI

- New protocol of UFH as anticoagulant of choice appears appropriate
- Contrary to literature, increase in incidence seen with:
  - UFH: Stent thrombosis and reinfarction
  - Bivalirudin: Major bleeding within 72 hours post-PCI

- Continue UFH monotherapy for all radial cases
- Protocol adjusted based on findings of activated clotting time

Discussion

- New protocol of UFH as anticoagulant of choice appears appropriate
- Contrary to literature, increase in incidence seen with:
  - UFH: Stent thrombosis and reinfarction
  - Bivalirudin: Major bleeding within 72 hours post-PCI
- Continue UFH monotherapy for all radial cases
- Protocol adjusted based on findings of activated clotting time
